In Brief

Hameed et al. report that selective knockdown of a thyroid hormone receptor in the mouse hypothalamus results in a phenotype of severe obesity, overeating, and reduced energy expenditure, which may be due to downstream changes in the expression of hypothalamic regulators of food intake.

Highlights

- The ventromedial hypothalamus (VMH) expresses thyroid hormone receptor beta (TRβ)
- In mice, selective knockdown of TRβ (TRβ⁻) in the VMH results in severe obesity
- The obesity is due to overeating (hyperphagia) and reduced energy expenditure
- TRβ⁻ mice have altered expression of hypothalamic regulators of food intake

SUMMARY

The obesity epidemic is a significant global health issue. Improved understanding of the mechanisms that regulate appetite and body weight will provide the rationale for the design of anti-obesity therapies. Thyroid hormones play a key role in metabolic homeostasis through their interaction with thyroid hormone receptors (TRs), which function as ligand-inducible transcription factors. The TR-beta isoform (TR β) is expressed in the ventromedial hypothalamus (VMH), a brain area important for control of energy homeostasis. Here, we report that selective knock-down of TR β in the VMH of adult mice results in severe obesity due to hyperphagia and reduced energy expenditure. The observed increase in body weight is of a similar magnitude to murine models of the most extreme forms of monogenic obesity. These data identify TR β in the VMH as a major physiological regulator of food intake and energy homeostasis.

INTRODUCTION

Energy homeostasis is regulated by neurotransmitters and by humoral factors including thyroid hormones, which act within the hypothalamus and systemically to regulate food intake (Coppola et al., 2007; Coll et al., 2007) and energy expenditure (Kim, 2008). The effects of the active form of thyroid hormone, 3,5,3'-L-triiodothyronine (T3), are mediated by two thyroid hormone receptors (TR α and TR β), encoded by *Thra* and *Thrb*, respectively (Brent, 2012).

Metabolic phenotypes have been described in mice and humans with TR mutations. Mice with heterozygous dominant-

negative mutations of TR α display a variety of metabolic phenotypes ranging from hypermetabolism, hyperphagia, and resistance to diet-induced obesity (Sjögren et al., 2007) to increased visceral adiposity, hypophagia, and impaired cold-induced adaptive thermogenesis (Liu et al., 2003). The variation in described phenotypes is likely to be due to the differing actions of individual mutant receptors on wild-type TR function (Ortiga-Carvalho et al., 2014). Humans with heterozygous dominant-negative mutations of TR α (resistance to thyroid hormone α [RTH α]) may be overweight or obese with reduced energy expenditure (Bochukova et al., 2012; Moran et al., 2013, 2014). Humans with heterozygous dominant-negative mutations of TR β have RTH β , resulting in high levels of circulating thyroid hormones and thyroid-stimulating hormone (TSH) due to impaired negative feedback of the hypothalamic-pituitary-thyroid axis (Ortiga-Carvalho et al., 2014). Humans with RTH β may be overweight and hyperphagic (Mitchell et al., 2010) despite features of hyperthyroidism such as tachycardia and raised energy expenditure due to T3 actions in TR α -responsive tissues. These extensive studies demonstrate that thyroid hormone is an essential regulator of food intake and energy expenditure. Despite this, clinical and global gene targeting studies cannot differentiate between the developmental and adult, or systemic and central, effects of thyroid hormones.

The ventromedial hypothalamus (VMH) is a critical region of the brain involved in energy homeostasis. TR β is the predominant TR isoform expressed in the VMH (Cook et al., 1992; Barrett et al., 2007), and previous studies suggest that thyroid hormones acting in the VMH regulate both food intake (Kong et al., 2004) and energy expenditure (López et al., 2010). Thus, we hypothesize that, in the VMH, TR β physiologically regulates food intake and body weight. To investigate this hypothesis directly, we used stereotaxic Cre-lox gene targeting to generate a VMH-specific model of TR β knockdown in adult mice.

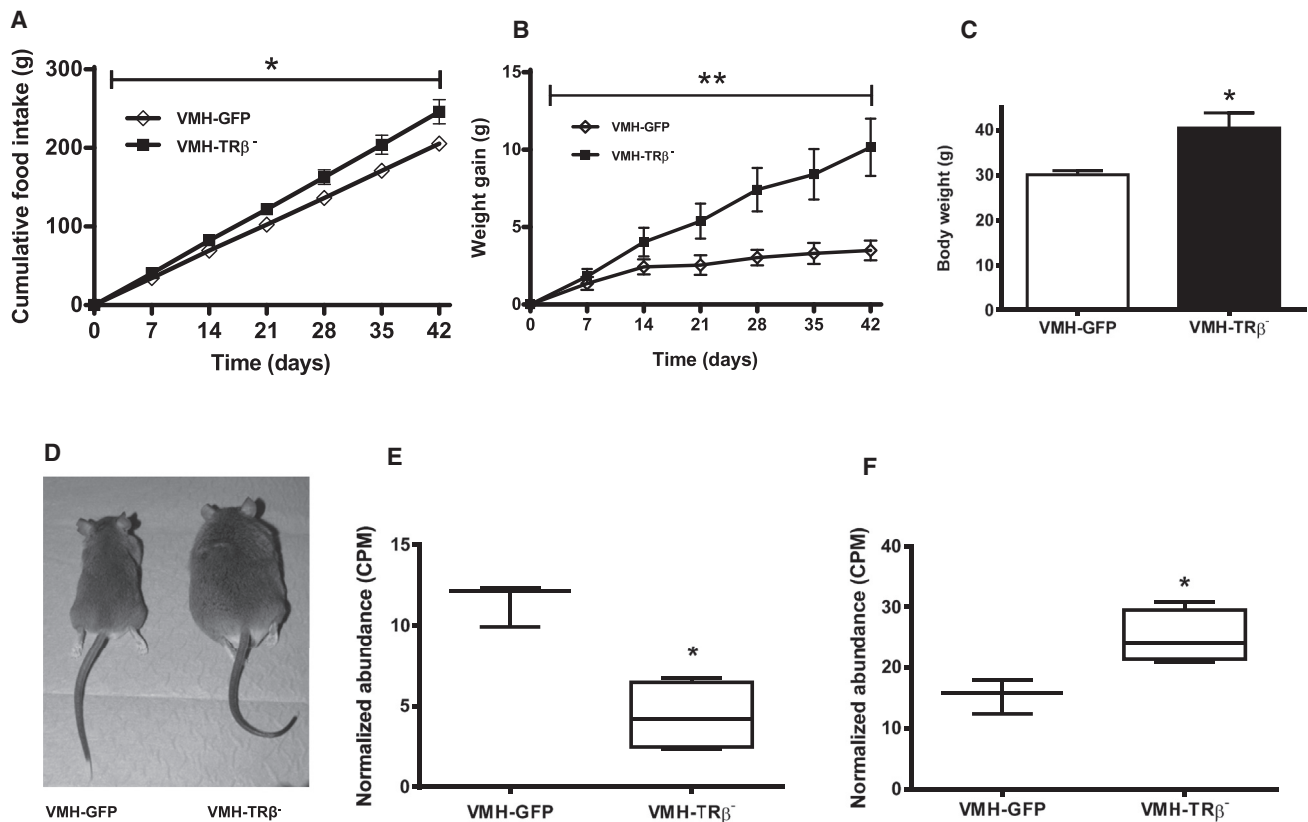

Figure 1. Effect of Reduced TRβ Expression in the VMH

(A) Cumulative food intake.
(B) Cumulative body weight change.
(C) Body weight on day 42.
(D) Photograph of VMH-GFP and VMH-TRβ⁻ mouse.
(E) Hypothalamic expression of *Pomc*.
(F) Hypothalamic expression of *Npy*.

In (A)–(C), the results are mean ± SEM; n = 10 for VMH-GFP and 11 for VMH-TRβ⁻. In (E) and (F), the results are median, and whiskers are minimum and maximum; n = 3 for VMH-GFP and 4 for VMH-TRβ⁻; *p < 0.05; **p < 0.01. Food intake and body weight were analyzed using a generalized estimating equation exchangeable correlation matrix and robust SEs (GEE), body weight data t test. See also Figures S1–S3 and Tables S1 and S2.

RESULTS

Tissue-Specific Knockdown of TRβ in the VMH in Adult Mice

We knocked down TRβ in the VMH of adult male mice using Cre-mediated excision of a floxed critical exon in the *Thrb* gene. This approach enabled temporally and spatially controlled reduction of TRβ expression specifically in the VMH of adult mice. This model eliminates the developmental consequences and abnormal systemic thyroid hormone levels that occur in global TRβ mutant mice (Ortiga-Carvalho et al., 2014) or in hypothyroid and thyrotoxic animals (Ishii et al., 2003; López et al., 2010).

The *Thrb*^{fllox} allele contains loxP sites flanking exon 5 of *Thrb* (Winter et al., 2009) (Figure S1A). Cre-recombinase-mediated excision of this critical exon results in inactivation of *Thrb* (Winter et al., 2009). Cre recombinase was introduced into the VMH of adult male *Thrb*^{fllox/fllox} mice by stereotaxic injection of recombinant adeno-associated virus (rAAV) expressing a Cre-GFP fusion

protein to generate mice with reduced TRβ expression in the VMH (VMH-TRβ⁻) mice. *Thrb*^{fllox/fllox} mice injected with rAAV encoding GFP into the VMH (VMH-GFP) were used as controls. Cre-mediated excision of the *Thrb*^{fllox} allele was confirmed by PCR of DNA from whole hypothalami of VMH-TRβ⁻ mice (Figure S1B). The *Thrb*^{fllox} allele was not excised in either the cerebellum or brainstem, indicating rAAV did not enter the ventricular system following stereotaxic injection (Figure S1B). Fluorescence microscopy and in situ hybridization (ISH) both confirmed transgene expression localized to the VMH in both groups of mice (Figures S2A and S2B). ISH using a probe specific for the floxed exon of *Thrb* demonstrated reduced expression within the VMH of VMH-TRβ⁻ mice compared with controls (Figures S2C and S2D).

Selective Knockdown of TRβ in the VMH in Adult Mice Results in Hyperphagia and Obesity

VMH-TRβ⁻ mice consumed more food and gained more weight than controls (Figures 1A and 1B). Weight gain in VMH-TRβ⁻

mice was three times greater than that of control mice by the end of the study (Figures 1C and 1D).

Whole hypothalami for RNA-sequencing (RNA-seq) analysis were collected from mice before significant changes in body weight had occurred. This was so that changes in expression are likely to be due to changes in thyroid hormone signaling rather than secondary effects of the increase in body weight and food intake. Differential expression analysis was performed (Table S1). Pathway analysis of differentially expressed genes revealed an over-representation of genes involved in dopamine, growth hormone, and leptin signaling pathways, as well as genes that are involved in neuronal activity regulation including long-term potentiation (LTP) and long-term depression (LTD); these results were qualitatively the same when the false discovery rate (FDR) for analysis was set between 0.001 and 0.1 (Table S2). Among the genes differentially expressed, *Pomc* expression was decreased (log Fc -1.38, p = 9.33 × 10⁻⁷) (Figure 1E), whereas *Npy* expression was increased

(log Fc 0.7, p = 9.42 × 10⁻⁶) (Figure 1F), whereas that of *Thrb* was not altered at the level of the whole hypothalamus (Table S1). Expression of steroidogenic factor 1 (*Nr5a1*), and uncoupling protein-2 (*Ucp2*), both of which are implicated in hypothalamic control of energy homeostasis (Majdic et al., 2002; Coppola et al., 2007), were unchanged. The differentially expressed genes were compared to those previously reported to be T3 responsive or directly regulated by T3 in cerebrocortical cells (Tables S1 and S2 and Figure S3) (Gil-Ibañez et al., 2017). Of the genes directly regulated by T3 in cerebrocortical cells, we identified 89 (~15%) were also significantly changed in our samples, among which was hairless (*Hr*). For genes regulated indirectly by T3, we identified 133 that were also changed (~9%).

Total, visceral, subcutaneous, and epididymal fat mass were all increased in VMH-TRβ^{-/-} mice compared to controls (Figures 2A–2E). In keeping with the increased adiposity, VMH-TRβ^{-/-} mice had a higher plasma leptin concentration than controls (Figure 2F).

Figure 3. Effect of Pair-Feeding on VMH-TRβ^{-/-} Mice

(A) Weight gain over the entire period of the experiment. During weeks 0–5, food intake of each VMH-TRβ^{-/-} mouse was limited to that of a weight-matched, VMH-GFP littermate. From weeks 5 to 9, ad libitum access to food was restored.

(B) Food intake during the pair-feeding period.

(C) Food intake during the ad libitum feeding period.

Results are mean ± SEM. n = 9; GEE, *p < 0.05; ***p < 0.001.

VMH-TRβ^{-/-} Mice Are Systemically Euthyroid

Alterations in circulating thyroid hormones affect food intake and body weight (Pijl et al., 2001). Measurement of plasma TSH, thyroxine (T4), and T3 confirmed that both VMH-TRβ^{-/-} and control mice were euthyroid (Figures S4A–S4C).

VMH-TRβ^{-/-} Mice Are Insulin Resistant but Do Not Show Changes in the Expression of Genes Involved in Hypothalamic Glucose Sensing

Obese VMH-TRβ^{-/-} mice had high levels of fasting insulin (Figure S4D), as expected. However, when glucose tolerance and insulin tolerance were tested before the development of obesity in the VMH-TRβ^{-/-} mice, there were no differences between the VMH-TRβ^{-/-} and VMH-GFP mice (Figures S4E and S4F). RNA-seq analysis did not identify changes in expression of hypothalamic glucose-sensing genes.

Obesity in VMH-TRβ^{-/-} Mice Is Not Due to TRβ Knockdown in Other Brain Areas

To confirm that the observed weight gain and hyperphagia in VMH-TRβ^{-/-} mice resulted from reduced TRβ expression in the VMH and not spread through the ventricular system into other brain regions, rAAV-Cre was injected into both lateral ventricles of *Thrb*^{fllox/fllox} mice; a control group of mice were injected with rAAV-GFP. There was no difference in cumulative food intake or body weight gain between these two groups (Figures S4G and S4H).

VMH-TRβ^{-/-} Mice Fail to Mount an Orexigenic Response to Administered T3

In order to validate loss of T3 signaling following TRβ inactivation in the VMH, we administered T3 to VMH-TRβ^{-/-} and VMH-GFP mice by subcutaneous injection. Over the 24-hr study period, T3 significantly increased food intake in VMH-GFP mice but VMH-TRβ^{-/-} mice failed to mount an orexigenic response to the administered T3 (Figure S4I).

VMH-TRβ^{-/-} Mice Do Not Become Obese When Pair-Fed to the Food Intake of Lean Controls

To investigate whether the hyperphagia contributed to, or was a consequence of, the development of the obese phenotype, VMH-TRβ^{-/-} mice were pair-fed to the food intake of a weight-matched VMH-GFP littermate for 5 weeks. During pair-feeding, there was no difference in cumulative body weight change or food intake (Figures 3A and 3B) or locomotor activity between the two groups.

After 5 weeks of pair-feeding, ad libitum access to food was restored for 4 weeks. Following restoration of free feeding, VMH-TRβ^{-/-} mice gained significantly more weight and consumed significantly more food than controls (Figures 3A and 3C).

VMH-TRβ^{-/-} Mice Have Reduced Energy Expenditure and Reduced Locomotor Activity

The contribution of changes in energy expenditure to the obese phenotype was investigated. Oxygen consumption (VO₂), carbon dioxide production (VCO₂), and locomotor activity were all decreased during the dark phase in ad libitum-fed VMH-TRβ^{-/-} mice both before and after the onset of obesity (Figures 4A–4C). By contrast, there was no difference in VO₂, VCO₂, or locomotor activity during the light phase (Figures 4A–4C). The decrease in nocturnal locomotion in VMH-TRβ^{-/-} mice was confirmed by behavioral analysis (Table S3). There was no difference in respiratory exchange ratio (RER) (Figure 4D) and no difference in brown adipose tissue (BAT) uncoupling protein-1 (*Ucp1*) expression (Figure 4E) between VMH-TRβ^{-/-} and control mice. In addition, VMH-TRβ^{-/-} mice have a normal body temperature (Figure S4J).

DISCUSSION

These studies identify hypothalamic TRβ as an important physiological regulator of appetite and body weight. Reduced TRβ expression in the VMH resulted in marked weight gain,

Figure 4. Energy Expenditure and Locomotor Activity in Mice with Reduced Expression of TRβ in the VMH

L, light phase; D, dark phase; 1, 1 week, and 6, 6 weeks, after recovery. Data are mean ± SEM (n = 5 VMH-GFP; n = 6 VMH-TRβ⁻); ANOVA with Student-Newman-Keuls analysis, **p < 0.01. See also Table S3.

comparable to severe forms of monogenic obesity (Tecott et al., 1995; Yaswen et al., 1999). The weight gain was a consequence of increased total body fat, and in particular a marked increase in subcutaneous and visceral white adipose tissue, the latter being an important risk factor for cardiovascular disease and diabetes (Montague and O’Rahilly, 2000).

VMH-TRβ⁻ mice ate more than control animals, and pair-feeding studies indicated that hyperphagia contributed directly to the obesity. Thus, VMH-TRβ⁻ mice remained lean when food intake was restricted but rapidly became obese when ad libitum feeding was restored.

Selective TRβ knockdown specifically in the VMH was confirmed by ISH and fluorescence microscopy. Although expression of *Thrb* was not reduced in the RNA-seq analysis, these samples are derived from whole hypothalami, and therefore the decrease in the level in the VMH is likely masked by the expression of *Thrb* throughout the rest of the sample. Indeed, the loss of TRβ function in the VMH was demonstrated by the failure of the expected orexigenic response to administered T3 in VMH-TRβ⁻ mice and further supported by the appropriate changes in genes directly regulated by T3. The possibility of the phenotype arising through virus spread to other CNS areas was excluded by rAAV-Cre injection into the lateral ventricles, which did not result in hyperphagia or obesity.

Previous work in rats has reported the acute orexigenic effect of exogenously administered T3 (Kong et al., 2004). Here, we show the endogenous effect of thyroid hormone action following selective TRβ knockdown. We suggest that our current work describes a local circuit within the VMH that physiologically regulates food intake as distinct from the feeding response to administered pharmacological doses of T3 analogous to the contrasting effects of NPY and PYY.

To investigate the underlying cause of hyperphagia in VMH-TRβ⁻ mice, hypothalamic gene expression patterns were determined by RNA-seq. The expression of *Pomc* and *Fto* were downregulated in the hypothalamus, whereas *Npy* was up-regulated. POMC and FTO are thought to inhibit food intake, whereas NPY stimulates food intake; therefore, these changes in expression may explain in part the phenotype observed.

Energy expenditure in VMH-TRβ⁻ mice was reduced both before and after the onset of obesity. There was no difference in BAT *Ucp1* expression between VMH-TRβ⁻ and control mice, suggesting that adaptive thermogenesis was unaffected. It is likely that changes in energy expenditure in VMH-TRβ⁻ mice resulted from decreased locomotor activity. The reduced locomotor activity is not a consequence of the obesity because it occurred before differences in body weight. In addition, during pair-feeding studies, the reduction in locomotor activity was lost,

possibly due to food-seeking behavior. This is likely to explain why body weight gain did not differ between the two groups before the restoration of ad libitum feeding. The energy expenditure and pair-feeding data indicate that both increased food intake and reduced locomotor activity contribute to obesity in VMH-TR β [−] mice.

In contrast to VMH-TR β [−] mice, global heterozygous TR β -knockout mice do not have an obese phenotype (Ortiga-Carvalho et al., 2014). This may be explained by the peripheral hyperthyroidism of these mice. In addition, the appetite circuits within the hypothalamus are subject to developmental plasticity and compensatory redundancy (Bouret et al., 2004; Horvath, 2005). For example, neither global deletion of *Agrp* and/or *Npy* nor ablation of arcuate AgRP/NPY neurons in neonatal mice results in a metabolic phenotype (Erickson et al., 1996; Qian et al., 2002; Luquet et al., 2005), whereas ablation of these neurons in adult mice produces profound hypophagia and starvation (Luquet et al., 2005; Gardiner et al., 2005; Bewick et al., 2005). Similar developmental compensation may occur in global TR β -knockout mice.

Studies using adenovirus-mediated expression of a dominant-negative TR (DN-TR) in the rat VMH have been reported (López et al., 2010). Although VMH DN-TR expression did not affect food intake or body weight in euthyroid animals, it prevented weight loss in thyrotoxic rats and resulted in reduced hypothalamic AMP-activated protein kinase (AMPK) expression (López et al., 2010). AMPK expression was unchanged in our model. DN-TR interferes with the actions of both TR α and TR β and exerts a marked repressive effect on gene transcription (Ortiga-Carvalho et al., 2014; Ferrara et al., 2012). By contrast, VMH-TR β [−] mice have only reduced TR β activity rather than the pathological repression of TR target genes that is present in animals expressing a dominant-negative receptor. This fundamental difference is likely to explain the contrasting phenotypes observed in these two models.

In summary, we have shown that hypothalamic TR β is an important physiological regulator of energy homeostasis because TR β knockdown in the VMH results in a phenotype of hyperphagia and severe obesity that is comparable to some of the most extreme forms of monogenic obesity (Tecott et al., 1995; Yaswen et al., 1999). Our findings provide insights into the central regulation of energy homeostasis by TR β that could be a target for anti-obesity therapies.

EXPERIMENTAL PROCEDURES

Animals

Thrb^{flox/flox} mice (Winter et al., 2009) were genotyped by PCR using specific oligonucleotide primers (Figure S1). Mice were housed in single cages and maintained under a controlled environment (temperature, 21–23°C; 12-h light–dark cycle, lights on at 07:00) with ad libitum access to chow and water (RM1; SDS Diets), except where stated. Male mice that were 8 weeks old at the start of procedures were used in all experiments. All animal studies were approved under the Animals (Scientific Procedures) Act (1986) (Project License Number 70_7229) and approved by the Animal Welfare and Ethical Review Body, Imperial College London, which is signed up to the ARRIVE (Animal Research: Reporting of In Vivo Experiments) guidelines.

rAAV Preparation

rAAV was produced (Grimm et al., 1998) and isolated (Zolotukhin et al., 1999), as previously described.

Confirmation of rAAV Transgene Expression, *Thrb* Excision, and Reduced TR β Expression in the VMH

Excision of the *Thrb*^{flox} allele within the hypothalamus was confirmed by PCR (Figure S1). ISH using a probe specific to the excised portion of TR β was performed to confirm reduced TR β expression within the VMH (Smith et al., 2008).

Measurement of Energy Expenditure

Metabolic parameters were measured by indirect calorimetry using an open-circuit Oxymax system of the Comprehensive Lab Animal Monitoring System (Columbus Instruments) (Gardiner et al., 2010).

RNA-Seq Analysis

RNA-seq analysis was performed using hypothalamic RNA from VMH-GFP (n = 3) and VMH-TR β [−] (n = 4) mice using next-generation sequencing (NGS) technologies (Imperial BRC Genomics Laboratory, Imperial College London). For further details, see Supplemental Experimental Procedures.

Statistical Analyses

Cumulative food intake and body weight data were analyzed using generalized estimating equations with exchangeable correlation matrix and robust SEs. Differences between two groups at individual time points were analyzed by unpaired t tests; for multiple comparisons, a Bonferroni correction was applied. Values from the behavioral study were analyzed using a one-way ANOVA followed by Kruskal-Wallis test. Data from the energy expenditure test were analyzed using a one-way ANOVA followed by a Newman-Keuls test. Plasma thyroid hormones were compared using Mann-Whitney U test. Differences between groups were considered statistically significant at the 95% confidence level (p < 0.05).

ACCESSION NUMBERS

The accession number for the RNA-seq data reported in this paper is GEO: GSE98690.

SUPPLEMENTAL INFORMATION

Supplemental Information includes Supplemental Experimental Procedures, four figures, and three tables and can be found with this article online at <http://dx.doi.org/10.1016/j.celrep.2017.05.066>.

AUTHOR CONTRIBUTIONS

W.S.D., S.R.B., J.H.D.B., G.R.W., and J.V.G. conceived of and supervised the project. S.H., M.P., W.S.D., S.A.R., Y.M., C.H., W.F., and J.V.G. conducted the majority of the experiments. S.A.R. and A.G. maintained the mice. A.G. and J.H.D.B. prepared the TR β probe. J.B. and J.A. performed the MRI study. G.S.H.Y., B.Y.H.L., and J.P.-W. performed the RNA-seq experiments and analysis. J.S. generated the *Thrb*^{flox/flox} mice. S.H., W.S.D., S.R.B., J.H.D.B., G.R.W., and J.V.G. wrote the manuscript. All authors discussed the results and commented on the manuscript.
